Introduction

- Gipps, P. (1981). *A behavioural car-following model for computer simulation*. Transportation Research Part B
- The Gipps model is a **reaction-time-based** car-following model, i.e., The speed and location of a vehicle is updated for every **reaction time** τ , i.e. $v_i(t + \tau) = V(t)$
- To implement the Gipps model, the Runge-Kutta scheme is needed, because it is given in a discrete-time formulation of speed

Introduction

Tianya Zhang, et al., Car-Following Models: A Multidisciplinary Review, arXiv:2304.07143v, 2024

- 5 Parameter settings

Model structure

- The Gipps model was proposed in the discrete-time generic formulation. The **speed function** reads

$$v_i(t + \tau) = V[x_i(t), x_{i-1}(t), v_i(t), v_{i-1}(t)]$$

- Thus, we solve it by following

$$\boxed{\dot{x}_i(t) = v_i(t + \Delta t) = V(\cdot)} \xrightarrow{\text{RK}} \boxed{x_i(t + \Delta t)}$$

Model detail

Combining the speed in **free-flow** and **congested** conditions, the speed function reads.

$$v_i(t + \tau) = \text{min} \left\{ v_i^{\text{free}}(t + \tau), v_i^{\text{cong}}(t + \tau) \right\}$$

It turns out the **smaller one** between the derived free-flow speed and congested speed.

Speed function in congested conditions

$v_i^{\text{cong}}(t)$ is proposed as follows

$$v_i^{\text{cong}}(t + \tau) = B_i \left(\frac{\tau}{2} + \theta \right) + \sqrt{B_i^2 \left(\frac{\tau}{2} + \theta \right)^2 + B_i \left\{ 2[x_{i-1}(t) - x_i(t) - L_{i-1}] - \tau v_i(t) - \frac{v_{i-1}(t)^2}{\hat{B}_{i-1}} \right\}}$$

- $B_i < 0$, deceleration;
- \hat{B}_{i-1} , braking rate of vehicle $(i - 1)$ estimated by vehicle i ;
- θ , safety margin time (talk later);
- L_i , vehicle length

Speed function in congested conditions

If we take $\theta = \frac{\tau}{2}$ as shown in [Wikipedia](#), the function (more recommended) is simplified as

$$v_i^{cong}(t + \tau) = B_i \tau + \sqrt{B_i^2 \tau^2 + B_i \left\{ 2[x_{i-1}(t) - x_i(t) - L_{i-1}] - \tau v_i(t) - \frac{v_{i-1}(t)^2}{\hat{B}_{i-1}} \right\}}$$

Speed function in free-flow conditions

The speed in free-flow conditions is fitted from **empirical data** as

$$v_i^{\text{free}}(t + \tau) = v_i(t) + 2.5A_i\tau \left(1 - \frac{v_i(t)}{V_i^{\text{max}}}\right) \left(0.025 + \frac{v_i(t)}{V_i^{\text{max}}}\right)^{\frac{1}{2}}.$$

- V_i^{max} , maximum speed;
- A_i is the acceleration.

Outline

- 1 Introduction
- 2 Model structure
- 3 Model detail
 - Speed function in congested conditions
 - Speed function in free-flow conditions
- 4 How is the model derived?
- 5 Parameter settings

Part-1: Leading Vehicle

- If vehicle $(i - 1)$ brakes **as hard as desirable** at time t , the vehicle will move to position x_{i-1}^* and **the speed drops to zero** as well, i.e.,

$$x_{i-1}^* = x_{i-1}(t) + \frac{v_{i-1}(t)^2}{2B_{i-1}} \quad (1)$$

- Refer to the well-known uniform acceleration, the Equations of Motion are written as follows,

$$\begin{cases} v_t = v_0 + at \\ s = v_0 t + \frac{1}{2}at^2 \end{cases}$$

- Given v_0 (i.e., $v_{i-1}(t)$), a (i.e., B_{i-1}), calculate s

Part-2: Following Vehicle

- Vehicle i will **not react until** time $(t + \tau)$, and will **stop** before reaching x_i^* :

$$x_i^* = x_i(t) + \frac{v_i(t) + v_i(t + \tau)}{2} \cdot \tau + \frac{v_i(t + \tau)^2}{2B_i} \quad (2)$$

- The term, $\frac{v_i(t) + v_i(t + \tau)}{2} \cdot \tau$, is the distance that the vehicle moves within the reaction time τ .
- It assumes **uniform acceleration**, also **second-order Runge-Kutta scheme**.

Part-3: Safety

- For **safety reasons**, vehicle i must ensure that

$$x_{i-1}^* - L_{i-1} \geq x_i^* \quad (3)$$

i.e., the rear bumper of the leader is in front of the front bumper of the follower.

Part-4: Human Error

- To allow the driver make mistakes, an **additional delay θ** is added. Thus, we have

$$x_{i-1}^* - L_{n-1} \geq x_i^* + \theta v_i(t + \tau) \quad (4)$$

Substituting Equation 1 and 2 into Inequality 4.

$$x_{i-1}^* = x_{i-1}(t) + \frac{v_{i-1}(t)^2}{2B_{i-1}} \quad (1)$$

$$\Downarrow$$

$$x_{i-1}^* - L_{i-1} \geq x_i^* + \theta v_i(t + \tau) \quad (4)$$

$$\Uparrow$$

$$x_i^* = v_i(t) + \frac{v_i(t) + v_i(t + \tau)}{2} \cdot \tau + \frac{v_i(t + \tau)^2}{2B_i} \quad (2)$$

$$\Downarrow$$

$$x_{i-1}(t) + \frac{v_{i-1}(t)^2}{2B_{i-1}} - L_{i-1} \geq v_i(t) + \frac{v_i(t) + v_i(t + \tau)}{2} \cdot \tau + \frac{v_i(t + \tau)^2}{2B_i} + \theta v_i(t + \tau)$$

In real traffic, it is possible for the driver of vehicle i to estimate all the values in Equation 1 and 2 except B_{i-1} (i.e., deceleration of the leading vehicle) by direct observation.

Thus B_{i-1} should be replaced by an estimate \hat{B}_{i-1} , and we finally obtain:

$$v_i(t + \tau) \leq B_i \left(\frac{\tau}{2} + \theta \right) + \sqrt{B_i^2 \left(\frac{\tau}{2} + \theta \right)^2 + B_i \left\{ 2[x_{i-1}(t) - x_i(t) - L_{i-1}] - \tau v_i(t) - \frac{v_{i-1}(t)^2}{\hat{B}_{i-1}} \right\}}$$

- 5 Parameter settings**

Parameter settings

Wilson (2001) conducted simulation experiments on a ring road:

- In the experiment of “stable uniform flow”
 - uniformly distributed initial positions;
 - total vehicle number $N = 50$;
 - $A_i = 1.7 \text{ m/s}^2$;
 - $V_i^{\max} = 30 \text{ m/s}$;
 - $B_i = -3 \text{ m/s}^2$;
 - $\hat{B}_{i-1} = -3.5 \text{ m/s}^2$;
 - $\tau = 2/3$;
 - $\theta = 1/3$;
 - $L_i = 6.5 \text{ m}$.
- In the experiment of “unstable uniform flow, leading to a travelling wave”,
 - \hat{B}_{i-1} is reduced to be 2.8 m/s^2

Following works

- **Prove that it is right:** the performance of the model is consistent with reality in the microscopic and macroscopic perspectives, such as
 - (Simulated or analytically deducted) fundamental diagram
 - Time-space of trajectories
 - Stability analysis
- Thus, proposing a CF model usually needs a number of work.
